

Quantitative Methods in Finance

Step 3: Forecast

Prof. Mike Aguilar

<https://www.linkedin.com/in/mike-aguilar-econ>

Last updated: April 14, 2024

Audience and Prerequisites

Audience:

- These notes were prepared for Kenan Flagler Business School's Daytime MBA program
- The setting is a 14 session course
- These notes serve as reference materials to complement our in-class work using computational tools

Prerequisites:

- Some knowledge of probability, statistics are expected
- Knowledge of finance in general, and asset pricing, in particular is expected

Motivating Case Study

- The motivating case study is portfolio allocation
- However, the concepts and tools are widely applicable to a range of settings within Finance
- We group the concepts into the following functional steps within our case study
 - ① Explore - Loading and cleaning data, EDA, etc..
 - ② Explain - Factor modeling, etc..
 - ③ Forecast - Time series models, etc...
 - ④ Protect - Portfolio allocation, risk measurement, etc..

- Throughout the slide deck you will see “Q”, which indicates a question to you, the reader
- You will also see “A”, which indicates the associated answer
- It is generally most efficient to learn this material through active participation. Whenever you encounter a “Q”, be sure to try and develop your answer before turning the page to the provided “A” answer
- I recommend reading through these slides before engaging in associated coding exercises

Outline

- 1 Anatomy of Forecasts
- 2 Averages and Time Trends
- 3 Time Series
- 4 Factor Models

Task: Forecast Asset Returns

International Business Machines Corporation (IBM) ★ Watchlist

157.495 +0.685(0.44%) NYSE - As of 11:16AM EST

Task: Forecast Asset Returns

$$E_t[r_{t+h}|t] = ?$$

h = forecast horizon

Common Return Forecasting Techniques

- Historical Averages
- Trend Extrapolation
- Time Series
- Factor Models

Forecast Evaluation Measures

$$r_{t+h|t} = \beta_1 + \beta_2 X_t + u_{t+h}$$

$$\hat{r}_{t+h|t} = \hat{\beta}_1 + \hat{\beta}_2 X_t$$

$$\hat{u}_{t+h} = r_{t+h} - \hat{r}_{t+h|t}$$

Forecast Evaluation Measures

$$r_{t+h|t} = \beta_1 + \beta_2 X_t + u_{t+h}$$

$$\hat{r}_{t+h|t} = \hat{\beta}_1 + \hat{\beta}_2 X_t$$

$$\hat{u}_{t+h} = r_{t+h} - \hat{r}_{t+h|t}$$

- $ME = \frac{1}{T} \sum_{t=1}^T \hat{u}_{t+h|t}$
- $MSE = \frac{1}{T} \sum_{t=1}^T \hat{u}_{t+h|t}^2$
- $RMSE = \sqrt{MSE}$
- $MAE = \frac{1}{T} \sum_{t=1}^T |\hat{u}_{t+h|t}|$
- $MAPE = \frac{1}{T} \sum_{t=1}^T \left| \frac{\hat{u}_{t+h|t}}{r_{t+h}} \right|$

- One Step Ahead vs Multi Step Ahead
- Lagged Regressors vs Time Series Models
- Static vs Dynamic Forecasting
- Backtesting: Training Period, Evaluation Period, Forecast Period

Forecast Types

One Step Ahead Forecasts

Date	Stock Returns
1/3/2000	0.07
1/4/2000	-0.03

"Current Period"

"Out of Sample"
"Forecast Period"

One Step Ahead Forecast;
With daily market data, that is one business day ahead.
If we had monthly data, that would be one month ahead.

The diagram shows a table of stock returns from January 3, 2000, to January 18, 2000. The first 14 rows (from 1/3/2000 to 1/14/2000) are highlighted in yellow and labeled as the "Training Period", "In Sample", and "Estimation Period". The 15th row (1/18/2000) is labeled as the "Current Period". The 16th row (1/18/2000) is labeled as the "Out of Sample" or "Forecast Period". A callout box explains that a "One Step Ahead Forecast" is one business day ahead with daily data, or one month ahead with monthly data.

Forecast Types

Multi Step Ahead Forecasts

Figure: IBM Intraday 2/5/15

Figure: Simulated Returns

Random Walk

$$r_t = r_{t-1} + \epsilon_t; \quad \epsilon_t \sim N(0, 1)$$

Definition

A moving average process of order q [MA(q)] can be represented by

$$r_t = \mu + \sum_{j=1}^q \alpha_j \varepsilon_{t-j} + \varepsilon_t$$

where $\varepsilon \sim N(0, \sigma^2)$ iid

Definition

An autoregressive process of order p [AR(p)] can be represented by

$$r_t = \sum_{j=1}^p \theta_j r_{t-j} + \varepsilon_t$$

where $\varepsilon \sim N(0, \sigma^2)$ iid

Definition

An ARMA(p,q) process can be represented by

$$r_t = \mu + \sum_{j=1}^p \theta_j r_{t-j} + \sum_{j=1}^q \alpha_j \varepsilon_{t-j} + \varepsilon_t$$

Definition

The k^{th} autocorrelation is defined as

$$\rho_k = \frac{\text{Cov}(y_t, y_{t-k})}{V(y_t)}$$

Definition

The k^{th} autocorrelation is defined as

$$\rho_k = \frac{\text{Cov}(y_t, y_{t-k})}{V(y_t)}$$

Definition

The k^{th} partial autocorrelation is defined as the estimate of θ_k in the AR(k) autoregression. For instance

- $\text{pac}_1 = \hat{\theta}_1$ from $y_t = \theta_1 y_{t-1} + \varepsilon_t$
- $\text{pac}_2 = \hat{\theta}_2$ from $y_t = \theta_1 y_{t-1} + \theta_2 y_{t-2} + \varepsilon_t$

Rules of Thumb

Rules of Thumb

An AR(p) process is described by

- 1 An ACF with slow decay
- 2 A PACF that is (close to) zero for lags larger than p

Rules of Thumb

An AR(p) process is described by

- ① An ACF with slow decay
- ② A PACF that is (close to) zero for lags larger than p

An MA(q) process is described by

- ① An ACF that is (close to) zero for lags larger than q
- ② A PACF with slow decay

Rules of Thumb

An AR(p) process is described by

- ① An ACF with slow decay
- ② A PACF that is (close to) zero for lags larger than p

An MA(q) process is described by

- ① An ACF that is (close to) zero for lags larger than q
- ② A PACF with slow decay

An ARMA process is described by

- Slow decay in both ACF and PACF

Example (Reading the Correlogram)

What model specification seems appropriate given the correlogram below?

Date: 07/11/07 Time: 11:27

Sample: 1996M04 2007M06

Included observations: 135

Autocorrelation	Partial Correlation	AC	PAC	Q-Stat	Prob	
		1	0.680	0.680	63.865	0.000
		2	0.549	0.160	105.71	0.000
		3	0.495	0.139	140.06	0.000
		4	0.466	0.108	170.72	0.000
		5	0.402	0.001	193.72	0.000
		6	0.331	-0.031	209.45	0.000
		7	0.305	0.034	222.91	0.000
		8	0.271	-0.003	233.64	0.000
		9	0.248	0.021	242.68	0.000
		10	0.239	0.042	251.10	0.000
		11	0.213	-0.005	257.89	0.000
		12	0.143	-0.096	260.98	0.000

Example (Reading the Correlogram)

The slowly decaying ACF and the spike at 1 lag for the PACF suggest an AR(1) might be appropriate.

- ① After fitting a potential model, conduct the "usual" overfitting and parameter tests of added variables (t and F tests).

Diagnostic Checking

- ① After fitting a potential model, conduct the "usual" overfitting and parameter tests of added variables (t and F tests).
- ② Plot the residuals and look for patterns as a sign of misspecification.

- ① After fitting a potential model, conduct the "usual" overfitting and parameter tests of added variables (t and F tests).
- ② Plot the residuals and look for patterns as a sign of misspecification.
- ③ Conduct a test of white noise (W.N.) on the residuals
 - H_0 : Residuals are W.N. vs H_a : Residuals are not W.N.
 - Test Statistic: $Q_K = T(T + 2) \sum_{k=1}^K \frac{1}{T-k} \hat{\rho}_k^2$, where $\hat{\rho}_k$ are the estimated autocorrelation coefficients of residuals $\hat{\varepsilon}_t$ at lag k .
 - Critical Value: $Q_K \sim \chi^2(K)$

- 1 After fitting a potential model, conduct the "usual" overfitting and parameter tests of added variables (t and F tests).
- 2 Plot the residuals and look for patterns as a sign of misspecification.
- 3 Conduct a test of white noise (W.N.) on the residuals
 - H_0 : Residuals are W.N. vs H_a : Residuals are not W.N.
 - Test Statistic: $Q_K = T(T + 2) \sum_{k=1}^K \frac{1}{T-k} \hat{\rho}_k^2$, where $\hat{\rho}_k$ are the estimated autocorrelation coefficients of residuals $\hat{\epsilon}_t$ at lag k .
 - Critical Value: $Q_K \sim \chi^2(K)$
- 4 Search for the smallest AIC and/or BIC values
 - $AIC = \ln(\hat{\sigma}_\epsilon^2) + 2(p + q)/T$
 - $BIC = \ln(\hat{\sigma}_\epsilon^2) + \log(T)(p + q)/T$

Outline

- 1 Anatomy of Forecasts
- 2 Averages and Time Trends
- 3 Time Series
- 4 Factor Models**

$$r_t - r^f = \alpha + \beta_1 F_{1,t} + \beta_2 F_{2,t} + \cdots + u_t$$

$$r_t - r^f = \alpha + \beta_1 F_{1,t} + \beta_2 F_{2,t} + \dots + u_t$$

CAPM $r_t - r^f = \alpha + \beta[r_t^M - r^f] + u_t$

Fama French $r_t - r^f = \alpha + \beta_1[r_t^M - r^f] + \beta_2 HML_t + \beta_3 SMB_t + u_t$

$$r_t - r^f = \alpha + \beta[r_t^M - r^f] + u_t$$

$$r_t - r^f = \alpha + \beta[r_t^M - r^f] + u_t$$

Caution: This model is not predictive.

$$r_t - r^f = \alpha + \beta[r_t^M - r^f] + u_t$$

Caution: This model is not predictive.

Solutions:

- $r_t - r^f = \alpha + \beta[r_{t-1}^M - r^f] + u_t$; Caution: Defies theory.
- Use subjective input for $E_t(r_{t+h}^M)$.
- Forecast $E_t(r_{t+h}^M)$ with a time series (or some other) model.

$$r_i - r^f = \lambda_0 + \lambda_1 \hat{\beta}_i + u_i$$

Forecast returns via: $\hat{r}_i - r^f = \hat{\lambda}_0 + \hat{\lambda}_1 \hat{\beta}_i$, where we use two $(\hat{\cdot})$'s to denote the second pass estimation.

Notice that there is no time series here.

Caution: Assumes β 's and λ 's are stable over time.
